AUTHORS: Barchukov, A.I. and Prokhinideyev, A.V.

TITLE: Details of a Radio Spectroscope for the Wavelengths from 2.5 to 5 mm

PERIODICAL: Radiotekhnika i elektronika, 1959, Vol 4, Nr 7, pp 1173 - 1179 (USSR)

ABSTRACT: The authors developed a number of devices suitable for the spectroscopy at mm lengths. The main item in the range of devices is the frequency multiplier. This employs crystal-diode frequency multiplication. The diode does not comprise the usual holder, but forms an integral part of a wave-guide system. The device of this type is shown in Figure 2. The mechanism which permits the adjustment of the crystal-whisker contact is in the form of a differential system permitting a displacement of 0.1 mm for one turn of the screw. However, even this mechanism is not sufficiently fine for wavelengths below 4 mm; in fact, it is necessary to be able to make adjustments of the order of microns. Figure 2 shows the details of the multiplier: 1) the adjustment mechanism for the crystal point; 2) the screw of the adjustment plunger;

Card1/3

SOV/109-4-7-11/25
Details of a Radio Spectroscope for the Wavelengths from 2.5 to
5 mm

3) crystal diode and 4) the contact spring. The details of the point of the contact spring are shown in Figures 3. The receiving head of the spectroscope is similar to that of the frequency multiplier. However, the operation of the receiving head is greatly dependent on the sharpness of the whisker point and its contact with the crystal. The next item of the spectroscope is a de-coupling device. This is in the form of a gyrator made from a thin rod of ferrite placed in the centre of a rectangular waveguide. The overall picture of the gyrator is shown in Figure 5. The absorption cell for the spectroscopic measurements was about 50 cm long and its electrode was supported by a holder made of teflon, having a thickness of 1 mm. The frequency at the mm waves could be measured by means of a heterodyne arrangement furnished with an additional frequency standard. Block schematic of the measurement circuit is shown in Figure 6. Another item necessary in the measurement is a frequency stabiliser. This employs

Card2/3

Details of a Radio Spectroscope for the Wavelengths from 2.5 to
5 mm

the circuit described by T.M. Murina (Ref 5) and its block schematic is shown in Figure 7. The spectroscope constructed by employing the above pieces of equipment could be used at frequencies up to 80 000 Mc/s. It was possible to use it to determine the rotational spectra of the molecules at frequencies up to 120 kMc/s, provided the absorption coefficient was $10^{-3}/\text{cm}$. The authors express their gratitude to A.M. Prokhorov for his valuable advice. There are 7 figures and 5 references, of which 4 are English and 1 Soviet.

TITLE: Investigation of the "spark" created in the air by a focused laser beam

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 47,
no. 5, 1964, 2003-2005

TOPIC TAGS: laser, ruby laser, air breakdown, dielectric breakdown, laser beam spark

ABSTRACT: Experimental investigation of air breakdown in the focus of a Q-switched ruby-laser beam yielded the following preliminary results. The laser, with a 30-megawatt peak power, had an output pulse half-width of 50 usec, a beam diameter of 12 mm, and an output beam energy of 1.5 J. The elongated spark produced in the air had an axial length of 10—15 mm; the threshold power sufficient to cause such a spark was found to be 5—10 megawatts. The entire air breakdown process was photographed with a high-speed SFR-2 camera at 625,000 frames per second. The resolution thus obtained was, however, inadequate to ana-

Card 1/2

lyze the most interesting initial period of the discharge. It was found that 40% of the laser-output energy passes through the focal point; the rest is absorbed in a small volume near the focus of the lens. The energy of the laser is liberated in an initial volume estimated at 10^{-4} cm^3 . The laser beam creates a radial shock wave which follows the pattern of channel formation in the usual spark discharges. A spectroscopic analysis showed the presence of singly charged NII and OII, as well as atomic nitrogen and an H_α line. In contrast to the spark, that involving the laser is characterized by a strong, continuous background, and by very broad lines, most of which are unresolved multiplets. These characteristics indicate a high electron concentration in the laser spark, reaching $2 \cdot 10^{18} \text{ cm}^{-3}$. The spark temperature, computed with a fairly low accuracy was 30,000—60,000K.

TITLE: Characteristics of a ruby laser with pulsed Q-modulation

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 48, no. 1, 1965,
106-110

TOPIC TAGS: ruby laser, laser, Q modulation, Q spoiler, laser experiment, laser beam spectroscopy, laser induced air breakdown

ABSTRACT: An experimental study has been made of a ruby laser with an output power of up to 50 MW for a pulse length of 40–50 nanoseconds. The ruby rod was 115 mm long, 12 mm in diameter, water cooled, and coated at the ends. The Q-modulator was a total-internal-reflection prism rotating at 425 rps. The semitransparent mirror was of the chemically deposited dielectric type, with reflection coefficient varying from 70 to 16% (substrate without coating). High-power pumping produced two separate output pulses. Gain was plotted as a function of pumping energy, using an elliptical reflector and an VFP-5000 lamp. The value of gain was determined with respect to the threshold power and various reflection coefficients

Card 1/2

L 25204-65

ACCESSION NR: AP5004381

of the mirrors without the Q-spoiler. It was possible to obtain a gain over 0.25 cm^{-1} in the central regions of the crystal with coated ends. Using the Q-spoiler, maximum energy per pulse was obtained with a K-8 glass substrate without dielectric coating for the mirror. The experiment thus confirmed the theoretical conclusion that high-transmittivity mirrors are preferable if gain is large enough and internal losses small. The spectrum of the laser output beam consisted of from 1 to 7 narrow lines, some of which broadened to a maximum of 0.15 cm^{-1} with increased pump power. The total width of the spectrum was 1.5 cm^{-1} at low power, and narrowed down to a mean of 0.6 cm^{-1} at higher power. A mirror substrate less than 3 mm thick produced a single line 0.1 cm^{-1} wide with very good directivity. This is considered one of the most convenient methods of producing narrow-line giant pulses at room temperature. Focusing of the beam is not

Mineralogical composition of calcium aluminate slags, and extraction of the aluminates they contain. J. N. Papeineau-Couture, Legis. Metal., 6, No. 7-8, 17-19 (1937); Chimie & Industrie, 41, 81. Slags with high Al_2O_3 and low SiO_2 (1-6%) contents give high yields of ext. Al_2O_3 ; but pulverulent slags high in CaO and contg. more than 6% SiO_2 give very low Al_2O_3 yields. Pulverulent slags are characterized by the presence of a considerable amt. of $2\text{CaO} \cdot \text{SiO}_2$. Of the aluminates, they contain chiefly of $5\text{CaO} \cdot 3\text{Al}_2\text{O}_5$ and $3\text{CaO} \cdot \text{Al}_2\text{O}_5$. The absence of monoaluminate (the richest in Al_2O_3) reduces considerably the Al_2O_3 yield from the slag. A. Papeineau-Couture

TITLE: On the Scattering of Electromagnetic Waves in a Plasma
(O rasseyanii elektromagnitnykh voln v plazme)

PERIODICAL: Zhurnal Eksperim. i Teoret. Fiziki, 1957, Vol. 33, Nr 3,
pp. 753-757 (USSR)

ABSTRACT: For the propagation of electromagnetic waves in the plasma a combined scattering of the waves by the density oscillations of the plasma is possible. The combined scattering is due to the fact that in the plasma a weakly damped electromagnetic oscillation may occur which is coupled with the variation of density of the plasma. The frequency of these oscillations is given by

$$\omega = \sqrt{4\pi n_0 e^2/m}$$

These oscillations lead to a periodical variation of the dielectric constant of the plasma. The intensity of the combined scattering of the electromagnetic field waves in the plasma is theoretically derived with and without the exterior homogeneous magnetic field. There are 4 Slavic references.

TITLE: Radiometallographic analysis of the process of phase hardening and aging of the alloy N27T2

SOURCE: Fizika metallov i metallovedeniye, v. 23, no. 1, 1967, 73-77

TOPIC TAGS: iron nickel alloy, titanium, x ray diffraction analysis, metal hardening, metal aging, phase composition / N27T2 Fe-Ni-Ti alloy

ABSTRACT: Considering that aging processes occur more effectively in Ti-containing Fe-Ni alloys compared with Ti-free Ni-Fe alloys it was of interest to analyze structural changes in an alloy of this kind during every stage of its heat treatment: quenching, phase hardening, phase hardening and aging. Accordingly, specimens of the alloy N27T2 (0.06% C, 0.48% Si, 0.40% Mn, 27.5% Ni, 2.68% Ti, 0.003% P, 0.011% S, with Fe as the remainder)(martensitic point -64°C; end of reverse martensitic transformation 730°C) were subjected to radiometallographic analysis (γ -Fe interference lines of debyograms). The structural changes in austenite

Card 1/2

UDC: 669.15•24

ACC NR AP7005753

were determined on the basis of changes in the width of the diffraction lines of (111) γ -Fe and (222) γ -Fe. The effect of aging was estimated according to changes in the lattice parameter a_{γ} of austenite. The various types of heat treatment employed were: quenching from 1050°C in water; phase hardening with cooling in liquid nitrogen (-196°C); phase hardening + aging at 450 and 650°C for 0.5, 3, 6 and 12 hr. Findings: the lattice parameter of phase-hardened austenite decreases compared with that of post-quenching austenite, which indicates that the temperature of limiting solubility of Ti for this alloy is somewhat above 800°C. As the aging process develops, the fine crystalline structure of the phase-hardened γ -solid solution becomes somewhat less "disperse" (isolated reflections can be perceived on the lines of the γ -phase) and the principal factor in the attainment of high hardness is the segregation of an excess phase (Ni_3Ti) and its rational distribution in the austenite matrix. The pattern of interference lines of the α -phase (martensite) obtained from austenite by means of subzero treatment and preliminary aging points to a higher "dispersity" of the fine crystalline structure of the martensite forming as a result of the aging. The high "dispersity" of the fine structure of the martensite arising on aging is due to the martensitic transformation in the phase-hardened austenitic matrix with fine-disperse particles of the excess phase. "The authors are profoundly grateful to K. A. Malyshev for his valuable assistance in the discussion of these findings." Orig. art. has: 3 figures, 1 table.
